

Ross Sea Length Scale from Observations

Introduction

- ▶ Use Conservative Temperature and potential density
- ▶ Use CTD, MVP and VPR observations
- ▶ Use 6 subsets of observations:

Ross Sea areas

- ▶ Southwest Ross Sea: Shelf water, sea ice melting
- ▶ Southeast Ross Sea: Shelf water, Ice shelf water
- ▶ Ross Ice Shelf: Ice shelf water, eddies
- ▶ Ross Bank:
- ▶ Northwest Ross Sea: Joides Trough
- ▶ Northeast Ross Sea: first eddies

Structure Function

Spatial Structure function

- ▶ Spatial lagged correlation
- ▶ Remove the mean and a linear trend in longitude
- ▶ Collect correlations by 1 km bins based on distance
- ▶ Assume isotropic structure
- ▶ Bootstrap estimate for variability (blue dashed lines)

Structure Functions: examples

If eddy structure is regular (periodic-alternating) in one direction, then a lag of 1 eddy diameter will result in a correlation of -1. So, the first zero crossing is about 0.5 eddy diameters.

Southwest Ross Sea area: avg conditions

Southwest Ross Sea area: T and σ at 10 m: MVP+VPR+CTD

Southwest Ross Sea area: count at 10 m: MVP+CTD(+VPR)

Southwest Ross Sea area: T and σ at 30 m: MVP+VPR+CTD

Southwest Ross Sea area: T and σ at 180 m: MVP+CTD

Ross Ice Shelf area: avg conditions

Ross Ice Shelf area: T and σ at 10 m: MVP+CTD

Ross Ice Shelf area: T and σ at 30 m: MVP+CTD

Ross Ice Shelf area: T and σ at 180 m: MVP+CTD

Joides area: T and σ at 30 m: MVP+CTD

Eastern area: T and σ at 30 m: MVP+CTD

Southeastern area: T and σ at 30 m: MVP+CTD

Ross Bank area: T and σ at 30 m: MVP+CTD

Length Scale from observations: Conclusions

Conclusions

- ▶ Density has longer scales than temperature.
- ▶ Deeper scales are longer than near-surface scales.
- ▶ Decorrelation scale is 40+ km.
- ▶ Eddy diameters are 30-50 km

Need to do similar analysis in Ross model solution.
